Definition (Weighted model counting)

Let \( \mathcal{P} \) be a set of propositional variables. Given a *weight function* \( w : \{0, 1\}^{\mathcal{P}} \to \mathbb{R}^+ \), the problem of **weighted model counting** is the problem of computing the summation of the weights of the models that satisfies a formula \( \phi \).

\[
\text{WMC}(\phi, w) = \sum_{I \in \{0, 1\}^{\mathcal{P}}} w(I) \cdot I(\phi)
\]

An alternative and equivalent formulation of weighted model counting is the following:

\[
\text{WMC}(\phi, w) = \sum_{I \in \{0, 1\}^{\mathcal{P}}} \begin{cases} w(I) & \text{if } I \models \phi \\ 0 & \text{otherwise} \end{cases}
\]
Suppose that we log what people buy in a supermarket:

<table>
<thead>
<tr>
<th>#</th>
<th>Itemsets</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>$a \ b \ c \ d$</td>
</tr>
<tr>
<td>1</td>

<tr>
<td>2</td>
<td>$d \ g$</td>
</tr>
<tr>
<td>1</td>
<td>$d$</td>
</tr>
<tr>
<td>4</td>
<td>$d \ g$</td>
</tr>
</tbody>
</table>

- Every combination of items can be seen as an interpretation on the set of propositions $a, b, \ldots, g$. and the number of times we observe such a combination could be considered the weight of the model.
- We have $2^7$ possible itemsets (interpretations $\mathcal{I}$), and we can assign to each a weight $w(\mathcal{I})$ which is the number of times an itemset has been observed.
Example

<table>

\[
\text{WMC}(a \land (b \lor c)) = 4 + 1 + 7 + 3 = 15
\]
\[
\text{WMC}(a \land g) = 0
\]
\[
\text{WMC}(a \land \neg g) = 4 + 1 + 7 + 3 = 15
\]
\[
\text{WMC}(a \rightarrow b) = 4 + 1 + 7 + 2 + 1 + 4 = 19
\]
Model counting vs. Weighted model counting

- in **model counting** each interpretation weights 1;
- In **WMC** instead, some models are more important than others, and it makes sense to associate a weight $w(I) \geq 0$ to each interpretation $I$.
- in **weighted model counting** each model of a formula counts for its weight $w(I)$
- this interpretation of weighted models can be used to represent some form of **uncertainty** about the world. E.g., by associating probability of a formula to be true.
- the weight $w(I)$ associated to the model $I$ can be interpreted in **probabilistically**; i.e., the higher the weight of a model the more likely the model;
Weight functions have been defined also in MaxSAT but there are some differences:

- In MaxSAT we allow negative weights, in WMC we don’t
- in MaxSAT Weights are used for defining an order on the interpretations;
- the nominal value of the weight function is not important
- two weight function are equivalent for MaxSAT if they define the same order on interpretations.
- in weighted model counting instead we are really interested in the nominal value of the weight of an interpretation.
The partition function $Z(w)$

**Proposition**

If $\phi$ is valid, then $\text{WMC}(\phi, w)$ is equal to $\sum_{\mathcal{I}: \mathcal{P} \to \{0,1\}} w(\mathcal{I})$

- The quantity $\sum_{\mathcal{I}: \mathcal{P} \to \{0,1\}} w(\mathcal{I})$ is called partition function of $w$.

$$Z(w) = \sum_{\mathcal{I}} w(\mathcal{I}) \quad (1)$$

- Computing $Z(w)$ is a source of complexity. In general we have to compute $w(\mathcal{I})$ for all the $2^n$ interpretations.
Specifying $W : \{0, 1\}^{\mathcal{P}} \rightarrow \mathbb{R}^+$

What is a compact way to represent the weight function?

- To explicitly defining the weights for each interpretation we need $2^{\mathcal{P}}$ parameters;
- Alternatively one can select $n$ formulas $\phi_1, \ldots, \phi_n$ and associate a weight to each one $w_1, \ldots, w_n$, and define
  \[
  w(I) = \prod_{I \models \phi_i} w_i
  \]
  or alternatively
  \[
  w(I) = \exp \left( \sum_{I \models \phi_i} w_i' \right)
  \]

- There is no free lunch. There are weight function that cannot be defined with less then $2^{\mathcal{P}}$ formulas.
- But in many cases it is possible. In this cases we say that $w$ factorizes w.r.t., $\phi_1, \ldots, \phi_n$. 
Consider the following two weight functions

<table>
<thead>
<tr>
<th>$p$</th>
<th>$q$</th>
<th>$w(I)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1.0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>2.0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>3.0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>6.0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>$p$</th>
<th>$q$</th>
<th>$w(I)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>2.0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>3.0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>5.0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>7.0</td>
</tr>
</tbody>
</table>

- The left weight function can be expressed using two weighted formulas; i.e. $3 : p$ and $2 : q$ using definition (2), indeed the weight of the model that satisfies both $p$ and $q$ is the product of the weight of $p$ and $q$, so we say that it factorizes.
- The second can be expressed with the weighted formulas $p \lor q : 2$, ...
Specifying \( W : \{0, 1\}^{|P|} \rightarrow \mathbb{R}^+ \) by literals

### Specifying weights on literals

\[
w(I) = \prod_{p \in P} w(p)^{I(p)} \cdot w(\neg p)^{1-I(p)}
\]

\[
WMC(\phi, w) = \sum_{I|=\phi} \prod_{p \in P} w(p)^{I(p)} \cdot w(\neg p)^{1-I(p)}
\]

\[
= \sum_{I|=\phi} \exp \left( \sum_{p \in P} v(p) \cdot I(p) + v(\neg p) \cdot (1 - I(p)) \right)
\]

where \( w : \text{Lit} \rightarrow \mathbb{R}^+ \) is a mapping from the set of literals (i.e., \( p \) and \( \neg p \) for \( p \) propositional variable) to positive real numbers. (\( v(\cdot) = \log(W(\cdot)) \))
Weighted Model counting

Example

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th>(w(x)) (\text{MCh}(I,x))</th>
<th>(w(\neg x)) (\text{MCh}(I,\neg x))</th>
<th>(w(I))</th>
<th>(Pr(I))</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1.2 1 3.2 1 0.4 1</td>
<td></td>
<td>1.536</td>
<td>0.08</td>
</tr>
</tbody>
</table>

\[
\text{WMC}(p \lor \neg q \rightarrow r) = w(001) + w(010) + w(011) + w(101) + w(111) \approx 14.26
\]

\[
\text{WMC}(\top) = w(000) + w(001) + \cdots + w(111) \approx 19.32
\]

\[
Pr(p \lor \neg q \rightarrow r) = \frac{\text{WMC}(p \lor \neg q \rightarrow r)}{\text{WMC}(\top)} \approx \frac{14.26}{19.32} \approx 0.74
\]
Weighted Model counting

Examples (Weights can be associated also to formulas)

\[ \neg(p \lor q) \rightarrow 0.0 \]
\[ p \rightarrow 0.1 \]
\[ p \lor r \rightarrow 1.2 \]
\[ q \rightarrow r \rightarrow 2.5 \]

\[ \Delta \text{ defines fresh variables} \]
\[ f_0 \leftrightarrow \neg(p \lor q) \]
\[ f_1 \leftrightarrow p \]
\[ f_2 \leftrightarrow p \lor r \]
\[ f_3 \leftrightarrow q \rightarrow r \]

\[ w' \]
\[ f_0 \rightarrow 0.0 \]
\[ f_1 \rightarrow 0.1 \]
\[ f_2 \rightarrow 1.2 \]
\[ f_3 \rightarrow 2.5 \]

\[
WMC(p \lor \neg q \rightarrow r \land \Delta) = \\
w(0011011) + w(0100000) + w(0110011) + w(1010111) + w(1110111) = \\
0 + 1 + 3 + 0.3 + 0.3 = 4.6
\]

\[
WMC(\Delta) = w(0001001) + w(0011011) + w(0100000) + w(0110011) \\
+ w(1000111) + w(1010111) + w(1100110) + w(1110111) \\
= 0 + 0 + 1 + 3 + 0.3 + 0.3 + 0.12 + 0.3 = 5.02
\]

\[
Pr(p \lor \neg q \rightarrow r \mid \Delta) = \frac{WMC(p \lor \neg q \rightarrow r \land \Delta)}{WMC(\Delta)} = \frac{4.6}{5.02} \approx 0.92
\]
Algorithm for Weighted Model Counting

- Exact method based on knowledge compilation. Generalization of model counting algorithm
- Approximated methods (not covered in the course): based on rectangular approximation\(^1\) or by reducing it to (unweighted) model counting\(^2\). See\(^3\) for a survey.

---

\(^1\)Ermon et al. 2013.
\(^2\)Colnet and Meel 2019.
\(^3\)Chakraborty, Meel, and Vardi 2021.
Let \( w \) be a weight function on the set of propositional variables of \( \phi \) and \( \psi \).

1. If \( \phi \) and \( \psi \) do not contain common propositional variables (\( \phi \land \psi \) is decomposable) then:

   \[
   \text{WMC}(\phi \land \psi, w) = \text{WMC}(\phi, w|_{P(\phi)}) \cdot \text{WMC}(\psi, w|_{P(\psi)})
   \]

2. If \( \phi \land \psi \) is unsatisfiable (\( \phi \lor \psi \) is deterministic) and \( \phi \) and \( \psi \) contains the same set of propositional variables (\( \phi \lor \psi \) is smooth) then

   \[
   \text{WMC}(\phi \lor \psi) = \text{WMC}(\phi) + \text{WMC}(\psi)
   \]

3. A formula is in smooth deterministic decomposable negated normal form (sd-DNNF) if
   - negation appears only in front of atoms (NNF);
   - every conjunction is decomposable;
   - every disjunction is smooth and deterministic.
Conversion to sd-DNNF

We use the same rules used for transforming in d-DNNF (Shannon’s expansion) with the following additional rule

- **Smoothing left:** For subformula $\phi \lor \psi$ with $p \in \text{props}(\psi) \setminus \text{props}(\phi)$
  apply this transformation

  $$\phi \land (p \lor \neg p) \lor \psi$$

- **Smoothing right:** For subformula $\phi \lor \psi$ with $p \in \text{props}(\phi) \setminus \text{props}(\psi)$
  apply this transformation

  $$\phi \lor \psi \land (p \lor \neg p)$$

This results in:

$$\left( \phi \land \bigwedge_{p \in \text{props}(\psi) \setminus \text{props}(\phi)} (p \lor \neg p) \right) \lor \left( \psi \land \bigwedge_{q \in \text{props}(\phi) \setminus \text{props}(\psi)} (q \lor \neg q) \right)$$
Reduction to sd-DNNF

Example

Smoothing \((a \land b) \lor (c \land \neg a)\) results in

\[(a \land b \land (c \lor \neg c)) \lor ((c \land \neg a) \land (b \lor \neg b))\]
Weighted model counting of sd-DNNF formulas

Every leaf (literal) is associated with its weight, and as in d-DNNF,
- at every $\land$-node we perform the product of the child nodes;
- at every $\lor$-node we perform the sum of the child nodes.

Example

Consider the following weighted literals: $a : 2$, $\neg a : 1$, $b : 5$, $\neg b : 3$, $c : 7$, and $\neg c : 1$. 

![Diagram of a weighted DNNF formula fulfilling the example conditions]
Interference between smoothing and determinism

Example

consider the formula \((a \land b) \lor c\), This formula is neither smooth nor deterministic. Should we try to first smooth it and then make it deterministic by applying Shannon’s expansion? or should we proceed in the opposite direction? Let’s analize the two cases:

- First **Smooth** then **determinism**

\[
(a \land b) \lor c \\
(((a \land b) \land (c \lor \neg c)) \lor (c \land (a \lor \neg a) \land (b \lor \neg b))) \\
(a \land b) \land (\top \lor \bot) \lor (\top \land (a \lor \neg a) \land (b \lor \neg b)) \land c \lor \\
((a \land b) \land (\bot \lor \top)) \lor (\bot \land (a \lor \neg a) \land (b \lor \neg b)) \land \neg c
\]

However notice that the formula in blue is not deterministic and we should repeat the application of Shannon’s expansion. This method of proceeding, though it is correct will result in exploding the formula.

Luciano Serafini (FBK, Trento, Italy)  Knowledge Representation and Learning  May 30, 2023  19 / 29
Interference between smoothing and determinism

Example

- First **determinism** then **Smooth**

\[
\begin{align*}
(a \land b) \lor c \\
((b \lor c) \land a) \lor (c \land \neg a) \\
((b \lor (c \land \neg b)) \land a) \lor (c \land \neg a) \\
((b \lor (c \land \neg b)) \land a) \lor (c \land \neg a \land (b \lor \neg b)) \\
(((b \land (c \lor \neg c)) \lor (c \land \neg b)) \land a) \lor (c \land \neg a \land (b \lor \neg b))
\end{align*}
\]

Shannon's exp. on \( a \)

Shannon's exp. on \( b \)

Smoothing

Smoothing

Let us use the resulting formula for weighted model counting of \((a \land b) \lor c\) with the weighted literals: \(a: 2\), \(\neg a: 1\), \(b: 5\), \(\neg b: 3\), \(c: 7\), and \(\neg c: 1\).
Interference between smoothing and determinism

Example

Consider the formula $(a \land b) \lor c$, This formula is neither smooth nor deterministic. Should we try to first smooth it and then make it deterministic by applying Shannon’s expansion? or should we proceed in the opposite direction? Let’s analyze the two cases:

- **First Smooth then determinism**

  
  
  $((a \land b) \land (c \lor \lnot c)) \lor (c \land (a \lor \lnot a) \land (b \lor \lnot b))$  
  $((a \land b) \land (\top \lor \bot)) \lor (\top \land (a \lor \lnot a) \land (b \lor \lnot b)) \land c \lor$  
  $((a \land b) \land (\bot \lor \top)) \lor (\bot \land (a \lor \lnot a) \land (b \lor \lnot b)) \land \lnot c$

However notice that the formula in blue is not deterministic and we should repeat the application of Shannon’s expansion. This method of proceeding, though it is correct will result in exploding the formula.
Interference between smoothing and determinism

Example

- First determinism then Smooth

\[(a \land b) \lor c\]

\[((b \lor c) \land a) \lor (c \land \neg a)\]

\[((b \lor (c \land \neg b)) \land a) \lor (c \land \neg a)\]

\[((b \lor (c \land \neg b)) \land a) \lor (c \land \neg a \land (b \lor \neg b))\]

\[((b \land (c \lor \neg c)) \lor (c \land \neg b)) \land a\] \lor (c \land \neg a \land (b \lor \neg b))

Let us use the resulting formula for weighted model counting of \((a \land b) \lor c\) with the weighted literals: \(a : 2, \neg a : 1, b : 5, \neg b : 3, c : 7,\) and \(\neg c : 1.\)
The weight function $w$ define the probability measure on the space of all the propositional interpretations of a finite set of propositional variable $\mathcal{P}$.

$$\Pr(\mathcal{I}) = \frac{w(\mathcal{I})}{\sum_{\mathcal{I} \in \mathcal{I}} w(\mathcal{I})} \quad (4)$$

For every formula $\phi$

$$\Pr(\phi) = \sum_{\mathcal{I}} \mathcal{I}(\phi) \cdot \Pr(\mathcal{I}) \quad (5)$$

By replacing (4) in (5) we obtain:

$$\Pr(\phi) = \frac{\text{WMC}(\phi, w)}{\text{WMC}(\top, w)} = \frac{1}{Z(w)} \text{WMC}(\phi, w) \quad (6)$$

Conditional probability can also be defined:

$$\Pr(\phi | \psi) = \frac{\text{WMC}(\phi \land \psi, w)}{\text{WMC}(\top, w)} = \frac{\text{WMC}(\phi \land \psi, w)}{\text{WMC}(\psi, w)} \quad (7)$$
Example

</tbody>
</table>

$\text{WMC}(\top) = 11.9$

$\text{WMC}(p \land q \rightarrow r) = 1.2 + 1.1 + 2.8 + 2.6 + 0.8 + 0.0 + 1.3 = 9.8$

$\text{WMC}((\neg p \land q) \equiv r) = 1.2 + 2.6 + 0.8 + 2.1 = 5.9$

$\Pr(p \land q \rightarrow r) = \frac{9.8}{11.9} \approx 0.82$

$\Pr((\neg p \land q) \equiv r) = \frac{5.9}{11.9} \approx 0.49$

$\Pr((\neg p \land q) \equiv r) \mid p \land q \rightarrow r = \frac{1.2 + 2.6 + 0.8}{9.8} \approx 0.47$
A Bayesian network on a set of random variables $\mathbf{X} = \{X_1, \ldots, X_n\}$ is a pair $\mathcal{B} = (G, Pr)$ is a pair composed of a directed acyclic graph $G = ([n], E)$ (where $[n] = \{1, \ldots, n\}$) and $Pr$ specifies the conditional probabilities

$$Pr(X_i = x_i \mid X_{\text{par}(i)} = x_{\text{par}(i)})$$

for every $X_i \in \mathbf{X}$. $\mathcal{B}$ uniquely define the join distribution on $\mathbf{X}$

$$Pr(\mathbf{X} = \mathbf{x}) = \prod_{i=1}^{n} Pr(X_i = x_i \mid X_{\text{par}(i)} = x_{\text{par}(i)})$$  \hspace{1cm} (8)
Bayesian networks

Example

The following simple Bayesian Network

\[
\begin{align*}
  \Pr(A) &= 1 \\
  \Pr(B | A = a) &= \\
  a & | P(B = 1 | A = a) \\
  0 & | 0.4 \\
  1 & | 0.9 \\
\end{align*}
\]

specifies the joint probability distribution \( P(A, B) = P(A) \cdot P(B | A) \)

\[
\begin{array}{c|ccc}
  a & b & P(A = a, B = b) \\
  \hline
  0 & 0 & 0.42 \\
  0 & 1 & 0.28 \\
  1 & 0 & 0.03 \\
  1 & 1 & 0.27 \\
\end{array}
\]
Encoding bayesian networks in \#SAT

\[
P(D) = 0.5
\]

\[
\begin{array}{c|c}
D & P(F\mid D) \\
\hline
\text{true} & 0.5 \\
\text{false} & 0.1 \\
\end{array}
\]

\[
\begin{array}{c|c}
D & P(G\mid D) \\
\hline
\text{true} & 0.7 \\
\text{false} & 0.2 \\
\end{array}
\]

\[
\begin{array}{c|c|c}
F & G & P(H\mid F, G) \\
\hline
\text{true} & \text{true} & 1.0 \\
\text{true} & \text{false} & 0.5 \\
\text{false} & \text{true} & 0.4 \\
\text{false} & \text{false} & 0.0 \\
\end{array}
\]

\[\text{Sang, Beame, and Kautz 2005.}\]
Semantics of BN

- nodes are propositional variables
  
  \[D : \text{John is Doing some work}\]
  \[F : \text{John has Finished his work}\]
  \[G : \text{John is Getting tired}\]
  \[H : \text{John Has a rest}\]

- tables associated to noses (conditional probability table (CPT)) specifies conditional probabilities of the node. w.r.t, its parents

\[
Pr(F = 1 \mid D = 1) = 0.5
\]
\[
P(F = 1 \mid D = 0) = 0.1
\]
\[
Pr(F = 0 \mid D = 1) = 1 - Pr(F = 1 \mid D = 1) = 0.5
\]
\[
Pr(F = 0 \mid D = 1') = 1 - Pr(F = 1 \mid D = 0) = 0.9
\]
\[
P(D) = 0.5
\]

| D | \( P(F|D) \) |
|---|---|
| true | 0.6 |
| false | 0.1 |

| D | \( P(G|D) \) |
|---|---|
| true | 0.7 |
| false | 0.2 |

| F | G | \( P(H|F, G) \) |
|---|---|---|
| true | true | 1.0 |
| true | false | 0.5 |
| false | true | 0.4 |
| false | false | 0.0 |

\[
\begin{array}{cccc|c}
| d | f | g | h | \Pr(D, F, G, H = d, f, g, h) \\
\hline
| 0 | 0 | 0 | 0 | 0.5 \cdot 0.9 \cdot 0.8 \cdot 1.0 = 0.360 \\
| 0 | 0 | 0 | 1 | 0.5 \cdot 0.9 \cdot 0.8 \cdot 0.0 = 0.000 \\
| 0 | 0 | 1 | 0 | 0.5 \cdot 0.9 \cdot 0.2 \cdot 0.6 = 0.054 \\
| 0 | 0 | 1 | 1 | 0.5 \cdot 0.9 \cdot 0.2 \cdot 0.4 = 0.036 \\
| 0 | 1 | 0 | 0 | 0.5 \cdot 0.1 \cdot 0.8 \cdot 0.6 = 0.024 \\
| 0 | 1 | 0 | 1 | 0.5 \cdot 0.1 \cdot 0.8 \cdot 0.4 = 0.016 \\
| 0 | 1 | 1 | 0 | 0.5 \cdot 0.1 \cdot 0.2 \cdot 0.0 = 0.000 \\
| 0 | 1 | 1 | 1 | 0.5 \cdot 0.1 \cdot 0.2 \cdot 1.0 = 0.010 \\
| 1 | 0 | 0 | 0 | 0.5 \cdot 0.4 \cdot 0.3 \cdot 1.0 = 0.060 \\
| 1 | 0 | 0 | 1 | 0.5 \cdot 0.4 \cdot 0.3 \cdot 0.0 = 0.000 \\
| 1 | 0 | 1 | 0 | 0.5 \cdot 0.4 \cdot 0.7 \cdot 0.6 = 0.084 \\
| 1 | 0 | 1 | 1 | 0.5 \cdot 0.4 \cdot 0.7 \cdot 0.4 = 0.056 \\
| 1 | 1 | 0 | 0 | 0.5 \cdot 0.6 \cdot 0.3 \cdot 0.5 = 0.045 \\
| 1 | 1 | 0 | 1 | 0.5 \cdot 0.6 \cdot 0.3 \cdot 0.5 = 0.045 \\
| 1 | 1 | 1 | 0 | 0.5 \cdot 0.6 \cdot 0.7 \cdot 0.0 = 0.000 \\
| 1 | 1 | 1 | 1 | 0.5 \cdot 0.6 \cdot 0.7 \cdot 1.0 = 0.210 \\
\end{array}
