Rotational motion
2 dimensions

We consider a particle of mass m constrained to move in a circular path of radius r in the xy-plane. The total energy is equal to the kinetic energy, because $V = 0$ everywhere. We can therefore write $E = \frac{p^2}{2m}$.

According to classical mechanics, the angular momentum, $J_z$ around the z-axis (which lies perpendicular to the xy-plane) is $J_z = \pm pr$, so the energy can be expressed as $J_z^2/2mr^2$. Because $mr^2$ is the moment of inertia, $I$, of the mass on its path, it follows that

$$E = \frac{J_z^2}{2I}$$

We shall now see that not all the values of the angular momentum are permitted in quantum mechanics, and therefore that both angular momentum and rotational energy are quantized.

The angular momentum of a particle of mass $m$ on a circular path of radius $r$ in the xy-plane is represented by a vector of magnitude $pr$ perpendicular to the plane.

The qualitative origin of quantized rotation
quantizzazione in modo qualitativo

\[ J_z = \pm pr \quad \quad p = \frac{h}{\lambda} \]

Lunghezza d’onda di De Broglie

Opposite signs correspond to opposite directions of travel. This equation shows that the shorter the wavelength of the particle on a circular path of given radius, the greater the angular momentum of the particle.

It follows that, if we can see why the wavelength is restricted to discrete values, then we shall understand why the angular momentum is quantized.

Suppose for the moment that \( \lambda \) can take an arbitrary value. In that case, the wavefunction depends on the azimuthal angle \( \phi \) as shown in Figure...
Rotational motion

quantizzazione in modo qualitativo

Two solutions of the Schrödinger equation for a particle on a ring. The circumference has been opened out into a straight line; the points at $\phi = 0$ and $2\pi$ are identical. The solution in (a) is **unacceptable** because it is not single-valued. Moreover, on successive circuits it interferes destructively with itself, and does not survive. The solution in (b) is **acceptable**: it is single-valued, and on successive circuits it reproduces itself.

Rotational motion
2 dimensions

quantizzazione in modo qualitativo

An acceptable solution is obtained only if the wavefunction reproduces itself on successive circuits, as in Fig. (b). Because only some wavefunctions have this property, it follows that only some angular momenta are acceptable, and therefore that only certain rotational energies exist. Hence, the energy of the particle is quantized. Specifically, the only allowed wavelengths are

$$\lambda = \frac{2\pi r}{m_l}$$

where $m_l = 0, 1, 2, \ldots$ NUMERO QUANTICO
Rotational motion

The angular momentum is therefore limited to the values

\[ J_z = \pm \frac{hr}{\lambda} = \frac{m_l hr}{2\pi r} = \frac{m_l \hbar}{2\pi} \]

\[ \lambda = \frac{2\pi r}{m_l} \]

where we have allowed \( m_l \) to have positive or negative values.

\[ J_z = m_l \hbar \quad m_l = 0, \pm 1, \pm 2, \ldots \]

Rotational motion
2 dimensions - Metodo formale

The hamiltonian for a particle of mass \( m \) in a plane (with \( V = 0 \)) is the same as that given in eqn 8.9:

\[
\hat{H} = -\frac{\hbar^2}{2m} \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right)
\]

and the Schrödinger equation is \( \hat{H}\psi = E\psi \), with the wavefunction a function of the angle \( \phi \). It is always a good idea to use coordinates that reflect the full symmetry of the system, so we introduce the coordinates \( r \) and \( \phi \) (Fig. 8.27), where \( x = r \cos \phi \) and \( y = r \sin \phi \). By standard manipulations we can write

\[
\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} = \frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{1}{r^2} \frac{\partial^2}{\partial \phi^2}
\]

(8.39)

However, because the radius of the path is fixed, the derivatives with respect to \( r \) can be discarded. The hamiltonian then becomes

\[
\hat{H} = -\frac{\hbar^2}{2mr^2} \frac{d^2}{d\phi^2}
\]

The moment of inertia \( I = mr^2 \) has appeared automatically, so \( \hat{H} \) may be written

\[
\hat{H} = -\frac{\hbar^2}{2I} \frac{d^2}{d\phi^2}
\]

(8.40)
Rotational motion
2 dimensions - Metodo formale

and the Schrödinger equation is

\[
\frac{d^2 \psi}{d\phi^2} = -\frac{2IE}{\hbar^2} \psi
\]

The normalized general solutions of the equation are

\[
\psi_{m_l}(\phi) = \frac{e^{im_l\phi}}{(2\pi)^{1/2}} \quad m_l = \pm \frac{(2IE)^{1/2}}{\hbar}
\]

The quantity \(m_l\) is just a dimensionless number at this stage.

We now select the acceptable solutions from among these general solutions by imposing the condition that the wavefunction should be single-valued. That is, the wavefunction \(\psi\) must satisfy a cyclic boundary condition, and match at points separated by a complete revolution: \(\psi(\phi + 2\pi) = \psi(\phi)\). On substituting the general wavefunction into this condition, we find

\[
\psi_{m_l}(\phi + 2\pi) = \frac{e^{im_l(\phi+2\pi)}}{(2\pi)^{1/2}} = \frac{e^{im_l\phi} e^{2\pi im_l}}{(2\pi)^{1/2}} = \psi_{m_l}(\phi)e^{2\pi im_l}
\]

As \(e^{i\pi} = -1\), this relation is equivalent to

\[
\psi_{m_l}(\phi + 2\pi) = (-1)^{2m_l} \psi_{m_l}(\phi)
\]

Because we require \((-1)^{2m_l} = 1\), \(2m_l\) must be a positive or a negative even integer (including 0), and therefore \(m_l\) must be an integer: \(m_l = 0, \pm 1, \pm 2, \ldots\). The corresponding energies are therefore those given by eqn 8.38a with \(m_l = 0, \pm 1, \pm 2, \ldots\).
